Classification

The Palmer Penguins dataset is a common resource for data exploration and demonstration of data analysis techniques. It was brought into the limelight by Dr. Kristen Gorman and the Palmer Station, Antarctica LTER, which is a member of the Long Term Ecological Research Network.

The dataset includes data for 344 penguins from three different species found on three islands in the Palmer Archipelago, Antarctica. The measured attributes in the dataset include:

1. **Species**: The species of the penguin, which can be Adelie, Gentoo, or Chinstrap.
2. **Island**: The island in the Palmer Archipelago, Antarctica, where the penguin observation was made. The options are Torgersen, Biscoe, or Dream.
3. **Culmen Length (mm)**: The length of the penguin's culmen (bill).
4. **Culmen Depth (mm)**: The depth of the penguin's culmen (bill).
5. **Flipper Length (mm)**: The length of the penguin's flipper.
6. **Body Mass (g)**: The body mass of the penguin.
7. **Sex**: The sex of the penguin.

The Palmer Penguins dataset is excellent for practicing data cleaning, exploration, and visualization.

You can find more information about the dataset, including a more detailed explanation of the variables, in this repository: allisonhorst/palmerpenguins.

For more in-depth studies or referencing, you might also consider checking out the publications from Palmer Station LTER: pal.lternet.edu/bibliography.
